ABSTRACT

We investigate the effects of adding structural guidelines to musical interactions for novices. We developed simple instrument where up to two people can play with two parameters (pitch & timber) by interacting with a 2D surface on an iOS device; both interactions are replicated on a shared public display. Structure can be added to the musical interaction thanks to squares that constraint pitch and timber, as well as a limit on the number of notes a user can play during a given amount of time. Participants were assigned by pair and each pair had to play a series of two duets, that shared the same background music. The control group played two duets without structure; the experimental group played the first duet with structure whereas the second duet was without structure. This design allowed us to compare within and between groups duets. We measured the quality of experience of the participants with a post experiment survey and an informal interview: it is not clear if structure leads to a better experience or not. We measured the quality of the music by launching a website that allowed users to compare two musics, which allowed us to rank the musics. We find that music with constraints is significantly better than music without constraints.

INTRODUCTION

Creating music with others is an enjoyable experience for those who know how to make music. However becoming musically proficient requires years of studying an instrument as well as the techniques and idioms of a specific musical tradition. With computer-based instruments the means of input is decoupled from the sound production, allowing designers to create instruments of varying complexity, including instru-

ments which are simple enough to be quickly learned and played by anyone, regardless of musical training.

We want to better understand what aspects of a new musical interaction make it attractive and fun for novices. We can think of musical interactions as being made up of two parts: the *instrument*, which is the means by which the player controls sound, and the *interaction*, which includes the actions that a player takes over time and how players interact with each other. A simple instrument which is easy to learn and play may not be enough for non-musically trained users. Being unfamiliar with possible musical goals or techniques for achieving them, they may still not know what to do with the instrument.

We hypothesize that adding structure, such as a game-like interaction which directs users within a musical parameters space, may provide a focus and context that helps players feel less inhibited and more expressive. We also predict that adding structure to musical interactions will lead to results which are more *musical*.

We created a simple instrument, and conducted an experiment in which users play duets together. We compare the situation in which the interaction is unstructured, that is players can play whatever they like, with an interaction that is *structured* by constraints that the player must satisfy.

RELATED WORK

For the last few decades a number of technology based musical interactions for novices have been created as installations to be played by the public in such places as museums and exploratoria. More recently, many new musical interactions for novices are being created as mobile apps, which are often played in private [1, 2]. One can also see games such as Guitar Hero and Rock Band as interfaces for restricted forms of musical performance.

Blaine and Fels [3] proposes a number of dimensions of collaborative musical interfaces for novices, and describes twenty-one contemporary collaborative interfaces with respect to these dimensions. Many of these interfaces combine auditory and visual elements. Often the interface for each player is identical or similar, allowing the player to easily understand the actions of other players. And most of these interfaces restrict the range of notes or sounds that an action creates such that the results are euphonic within the greater

musical context. (This is an instance of the commonly experience tradeoff between the range of expressivity that an instrument allows and the ease with which it can be quickly learned.) The instrument and interactions that we designed for this study also share these characteristics.

OUR STUDY

Overview

The goal of our experiment is to find out whether adding structure improves novice users experience of a new musical interaction, and whether this improves the quality of the resulting music. We created a simple electronic instrument that is intended to be easily and quickly learned. We also designed two variations of a musical interaction. In the unstructured interaction, pairs of users, each playing the instrument, perform a duet together along with some musical accompaniment. In the structured interaction players also play a duet to the same accompaniment, but with the addition of constraints which impose structure on the interaction.

We will first describe the instrument, then the interactions, and lastly the particulars of the experiment.

Design of Instrument and Interaction

The Instrument The instrument we created is controlled by an iOS app running on an iPhone or iPod Touch. The app has a single 2D touch area, and users can play a note by touching this area. When the touch location changes a new note is played, allowing strings of notes to be played by touching and dragging. The interface recognizes only one touch at a time. [maybe pic of iPhone interface here.]

A note consists of a short synthetic tone with a sharp attack followed by a quick decay. The vertical location of the players touch controls the pitch of the note (higher placement leads to higher pitch and vice versa), and the horizontal location controls the timbre by changing the balance of high and low frequencies.

The Interaction The musical interaction is designed for two players. Each plays their own instrument with a their own iPhone controller, and each instrument has a slightly different tone (a sawtooth wave for one player and a square wave for the other.) There is a shared public display where players as well as any bystanders can see their own actions as well as those of their partner. The display appears as a single large rectangle mirroring the touch area on the iPhone controller. Notes played on either instrument appear as colored circles in the rectangle, with a different color for each player [ADD FIGURE]

Playing a Duet When users play a duet there is a background musical accompaniment consisting of some chords and a drum pattern. The duet consists of 8 “patterns” of four measures each. At a tempo of 100 beats per minutes a duet lasts about a minute and twenty seconds. A bar at the top of the display shows time progressing through each pattern, as well as the number of patterns left in the song.

The notes that the instruments play are constrained to a scale which sounds good with the chords of the duet. Also the timing of notes are constrained to always fall on 16th note intervals of the duets rhythm. As a result the music performed

will always sounds musically consistent.

Adding Constraints to Create Structure The instrument can be thought of as enabling three basic musical dimensions: note pitch (controlled by vertical location), note timbre (horizontal location), and the density of notes (a function of how frequently notes are played.) We create structure by directing the players into different areas of this musical space at different times. During structured duets blue squares appear on the display [ADD FIGURE]). The players are encouraged to play within these squares, and if they play outside of them their sounds becomes distorted. The boundaries of the structure squares change for each 4-bar pattern in the music. This serves to constrain the first two musical dimensions.

We control the third dimension, note density, by constraining the number of notes that a player can play during each pattern. Colored bars on either side of the screen indicate the number of notes left to each player for the current pattern. [ADD FIGURE]

Implementation The instrument is controlled with a custom layout for the TouchOSC iOS app which sends Open Sound Control (OSC) messages over UDP to a computer. On the computer a program written in ChucK performs all the sound synthesis and sequencing as well as the logic for the structural constraints. The display is created by a Processing program on the same computer.

THE EXPERIMENT

We performed a between subjects experiment. Participants were grouped into pairs, and pairs were assigned to either the control or experimental condition. We had eight pairs of participants divided into four control pairs and four experimental pairs. All participants were university students.

The experiment proceeded as follows for each pair of participants: The instrument was briefly demonstrated, and participants then had up to two minutes to learn the instrument by playing freely with no accompanying music. Both participants learned their instrument simultaneously and could hear each other and see each others actions on the display. Following learning the instrument, the first duet was performed. The first duet was unstructured for the control group and structured for the experimental group.

Following the first duet there was a brief pause, and the control group was given brief verbal suggestions for ways to structure their interactions. The suggestions were equivalent to what the experimental group might infer from the constraints of the structured interaction.

Participants then performed a second duet together. The musical accompaniment for the second duet was the same as for the first. In the second duet both the control and experimental groups were given the unstructured interaction. The experiment is represented on figure [?].

This design allows as to compare the duets between and within groups. Given our hypotheses, we expected to find that in the first duet the experimental group was more enjoyable, due to the context provided by the structure, and that they created better music than the control group. We ex-

Figure 1: The experiment. The control group 1) has a short period of training, 2) plays a duet without structure, 3) is given verbal instructions, 4) plays a second duet without structure. The experimental group 1) has a short period of training, 2) plays a duet with structure, 3) has a short pause, 4) plays a second duet without structure.

pected that within the control group the second duet would be less enjoyable due to the loss of context when the structure was removed.

We also expected that in the second duet the experimental group would perform musically as well or better than the control group, due to inferring principles of musical interaction from the structured interaction.

RESULTS

From the Survey

After the experiment, the participants had to answer a survey. For each duet, we asked them to evaluate on a Likert scale (from 1 to 7) the following metrics:

- their confidence,
- their enjoyment,
- how much they took the other player into account,
- how much they think the other player took them into account,
- and the quality of the music.

For each group, we compared the scores assigned for both duets. We find that people from the control group enjoyed the second duet significantly more than the first one ($t(14) = 2.89, p = 0.006$), took their partner into account significantly more in the second duet than in the first one ($t(14) = 2.09, p = 0.028$), and thought that the music was significantly better in the second duet than in the first ($t(14) = 3.47, p = 0.002$).

Furthermore, we also calculated the increase of these metrics between duet 1 and duet 2, and compared the difference between the control and the experimental group. We find two results:

- the increase in the enjoyment from duet 1 to duet 2 is significantly greater in the control group than in the experimental group ($t(14) = 1.85, p = 0.043$),
- the increase in the perceived music quality from duet 1 to duet 2 is significantly greater in the control group than in

the experimental group ($t(14) = 2.17, p = 0.024$).

These results correlate and confirm the previous one by removing any bias that could have been introduced by the mean: for the control group, the experience was significantly better in the second duet than in the first one.

Crowdsourcing the Evaluation of the Musical Quality

One of the main challenges we had to face was to evaluate the quality of the music. Indeed, aesthetics is intrinsically subjective. Removing the biases introduced by personal preferences can be done by having the evaluation done by a large number of people.

Consequently, we launched the MusicMash website that asks the users to compare two songs and tell which one is better. This allowed us to rank the music that were produced in the first duet (by the control and the experimental group), and on the other hand, the musics that were produced in the second duet (idem). In order to rank the musics, we used the Elo rating system which allows to compute the relative quality of the musics.

In 48 hours, we gathered 474 evaluations, coming from 114 different IP addresses. Table 1 shows the ranking among the songs in duet 1. With a standard deviation of 44.05 and a mean of 1500 in the Elo scores of these songs, it means that the music produced by group 3 is almost two standard deviations below the mean ($\Delta = 86$). For that reason, we think we can reasonably assume that this data point is an outlier, and remove it from our dataset.

Figure 2 shows the average Elo score of the music performed with structure, and the music performed without structure. The average score of the music performed with structure is significantly greater than the score of the music performed without structure ($t(6) = 3.55, p = 0.006$). Put differently, adding structure to the musical interactions led to better music.

Analyzing Notes

We recorded all note data during the duet performances, and calculated three metrics to quantify the musical parameter of note density. The percent of notes played tells us how many total notes were played. The percent of time with no notes tells us how often neither player was playing, *i.e.* how much

Figure 2: Note repartition in the different duets.

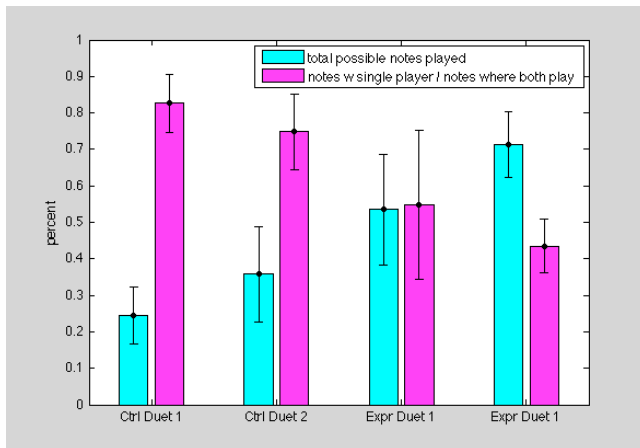

Figure 3: Note repartition in the different duets.

space the players left. And the percent of notes with only one player tells is the proportion of time when a note was played that only one player was playing at that time, which tells us how much the players took turns. Each of these metric has an obvious trend when we plot from the duets from the Control group to those of the Experiment group, as we can see on figure 3. The first increased, while the second two decrease. A significant difference between these results appears when we compare the second duet of the control with that of the experiment. The control group played fewer notes ($p = 0.048$) and had higher proportion of single notes, *i.e.* they exhibited more turn taking ($p = 0.035$). In some sense this suggests that the control group played better music during the second duet.

DISCUSSION

Our goal was to better understand musical interactions for novices by dividing the interface into instrument and interactions, and then to investigate the effect of adding structure to the interaction. Our crowd-sourced evaluation of the musical results showed that adding structure clearly leads to better music. However it is less clear whether adding structure led to a better experience for the user.

From the survey we found that users who played two unstructured duets had no significant change in their experience between duets, while those who had a structured interaction in the first duet had a better experience in the second unstructured duet. We can interpret this in either of two conflicting ways. The first is that the second duet was better because the previous structured interaction increased the users confidence in performing duets with the instrument. From the interviews a few people reported that they liked the structural constraints because like a game, they provided goals, but none reported that they thought of the constraints during the second duet.

The second interpretation of the increase in enjoyment from structured to unstructured interaction, is that the structured interactions were not as enjoyable as unstructured. A number of participants reported that it was difficult to quickly understand all the visual feedback being provided during structured interactions. Though we attempted to design a simple instrument with simple interaction constraints, the net effect was to create a complicated interaction.

Despite any differences between the interaction types, almost all participants reported enjoying the experience, and being pleased with being able to easily make relatively good-sounding music.

FUTURE WORK

The first

The survey result is interesting. We have considered all the duets as real performances. However, people from the experimental group reported that they enjoyed the experience significantly better in the second duet (unstructured) than in the first (structured), whereas there was no significant difference in the control group (where both duets are unstructured). If the level of enjoyment for the first duet is the same in both groups (which the results of our survey seems to correlate), it may be the case that structure is an excellent training for people. It would be interesting to study if people enjoy more their music after a training period with structure rather than after a training period without structure.

Similarly, it would be interesting to study if the structure in the first duet actually teaches musical principles (consciously or subconsciously) to the novices. Such a study could consist in measuring the behavioral change between interactions with structure and

Enjoyment of the experience: - instrument may be badly designed, especially note density. - ordering effects

Does the structure on the first duet really teach principles to organize music?

To be written.

CONCLUSION

In this study, we investigated the effects of adding structural guidelines to musical interactions for novices. The instrument we designed allowed novices to play the music with simple interactions, and we were able to constraint those interactions by adding structure. The participants

We were able to compare the music produced in each of these groups. We found that the quality of the music is significantly greater with structure rather than without structure. The results about how the novices enjoyed their experience are less clear. The results of the survey tend to show that people preferred the experience

We developed simple instrument where up to two people can play with two parameters (pitch & timber) by interacting with a 2D surface on an iOS device; both interactions are replicated on a shared public display. Structure can be added to the musical interaction thanks to squares that constraint pitch and timber, as well as a limit on the number of notes a user can play during a given amount of time. Participants were assigned by pair and each pair had to play a series of two duets, that shared the same background music.
